## Rules for Assigning Oxidation Numbers

1. The oxidation number of an element in any elementary substance is zero.

For example, the oxidation number of chlorine in $\mathrm{Cl}_{2}$, phosphorus in $\mathrm{P}_{4}$, and sulfur in $\mathrm{S}_{8}$ is 0 .
2. The oxidation number of an element in a monatomic ion is equal to the charge on that ion.

| Compound | $\underline{\text { Ions }}$ | Oxidation No. |
| :---: | :--- | :---: |
|  | $\mathrm{Na}^{+}$ | +1 |
|  | $\mathrm{Cl}^{-}$ | -1 |
| $\mathrm{Al}_{2} \mathrm{O}_{3}$ | $\mathrm{Al}^{3+}$ | +3 |
|  | $\mathrm{O}^{2-}$ | -2 |

3. Certain elements have the same oxidation number in almost all their compounds.
> Group 1 always forms +1 ions: $\mathrm{Li}^{+}, \mathrm{Na}^{+}, \mathrm{K}^{+}$, etc. oxidation number +1

- Group 2 always forms +2 ions: $\mathrm{Mg}^{2+}, \mathrm{Ca}^{2+}$, etc. oxidation number +2
- Fluorine always has an oxidation number of -1 .
- Oxygen has oxidation number of -2 except in peroxides, $\mathrm{O}_{2}{ }^{2-}$, (examples: $\mathrm{H}_{2} \mathrm{O}_{2}, \mathrm{Na}_{2} \mathrm{O}_{2}$ ) and in superoxides, $\mathrm{O}_{2}^{-}$, (example: $\mathrm{KO}_{2}$ ) where it has oxidation numbers of -1 and $-1 / 2$, respectively.
- Hydrogen has oxidation number of +1 except in hydrides, $\mathrm{H}^{-}$, (examples: $\mathrm{NaH}, \mathrm{CaH}_{2}$ ) where it has an oxidation number of -1 .

4. The sum of the oxidation numbers of all the atoms in a neutral species is zero; in an ion, it is equal to the charge of that ion.
$\mathrm{Li}_{3} \mathrm{~N}$ : ox. no. of $\mathrm{Li}^{+}$is +1
$3(+1)+$ ox. no. of $N=0$
ox. no. of $\mathrm{N}=-3$
$\mathrm{ClO}_{2}^{-}$: ox. no. of O is -2
ox. no. of $\mathrm{Cl}+2(-2)=-1$
ox. no. of $\mathrm{Cl}-4=-1$
ox. no. of $\mathrm{Cl}=+3$

## Rules for Balancing Redox Equations

We will use the example:

$$
\mathrm{Cu}(\mathrm{~s})+\mathrm{NO}_{3}^{-}(\mathrm{aq}) \rightarrow \mathrm{Cu}^{2+}(\mathrm{aq})+\mathrm{NO}_{2}(\mathrm{~g}) \quad \text { (acidic solution) }
$$

## 1. Split the equation into two half-equations, one for oxidation and one for reduction.

Remember: oxidation is an increase in oxidation number and reduction is a decrease in oxidation number.

Using the rules for determining oxidation numbers (ox. no.):

$$
\begin{array}{rrr}
\mathrm{Cu}+\mathrm{NO}_{3}^{-} \\
\text {ox. no. } \mathrm{Cu}=0 \mathrm{Cu}^{2+}+ & \mathrm{NO}_{2} \\
\mathrm{~N}=+5 \\
\mathrm{O}=-2 & \mathrm{Cu}=+2 & \mathrm{~N}=+4 \\
\mathrm{O}=-2
\end{array}
$$

reduction half equation: $\mathrm{NO}_{3}{ }^{-} \rightarrow \mathrm{NO}_{2}$ (ox. no. of N decreases: $+5 \rightarrow+4$ ) oxidation half-equation: $\mathrm{Cu} \rightarrow \mathrm{Cu}^{2+}$ (ox. no. of Cu increases: $0 \rightarrow+2$ )
(Notice that we have left out $\mathrm{H}^{+}$and $\mathrm{H}_{2} \mathrm{O}$ for acidic solution or $\mathrm{OH}^{-}$and $\mathrm{H}_{2} \mathrm{O}$ for basic solution for now. We will add these in later as we need them.)

## 2. Balance one of the half-equations with respect to both atoms and charge.

First we balance the oxidation half-equation since it is easier.
(a) Balance the atoms of the element being oxidized.

The atoms of Cu are already balanced.

$$
\mathrm{Cu} \rightarrow \mathrm{Cu}^{2+}
$$

(b) Balance oxidation number by adding electrons.

For an oxidation half-equation, we add electrons to the right. Since the oxidation number of copper increases from 0 to +2 , we add two electrons to the right.

$$
\begin{aligned}
& \\
& \\
& \mathrm{Cu} \rightarrow \mathrm{Cu}^{2+}+2 \mathrm{e}^{-} \\
& \text {ox. no.: } \\
& 0
\end{aligned}(+2 \quad-2=0)
$$

The oxidation half-equation is now balanced since there are no other atoms to balance.

## 3. Balance the other half-equation with respect to both atoms and charge.

Next we balance the reduction half-equation.

## (a) Balance the atoms of the element being reduced.

The N atoms are already balanced, and O atoms will be balanced later.

$$
\mathrm{NO}_{3}^{-} \rightarrow \mathrm{NO}_{2}
$$

(b) Balance oxidation number by adding electrons.

For an reduction half-equation, we add electrons to the left. Since the oxidation number of nitrogen decreases from +5 to +4 , we add one electron to the left.

$$
\begin{array}{r}
\mathrm{NO}_{3}^{-}+\mathrm{e}^{-} \rightarrow \mathrm{NO}_{2} \\
\text { ox. no.: } \quad(+5-1=+4)+4
\end{array}
$$

## (c) Balance charge by adding $\mathrm{H}^{+}$ions in acidic solution.

(Note: If this were basic solution, we would balance charge by adding $\mathrm{OH}^{-}$ions to the more positive side of the equation.)

$$
\begin{array}{ll} 
& \mathrm{NO}_{3}^{-}+\mathrm{e}^{-} \rightarrow \mathrm{NO}_{2} \\
\text { charge: } & (-1-1=-2) 0
\end{array}
$$

We balance the charge with positive $\mathrm{H}^{+}$ions by adding two $\mathrm{H}^{+}$ions to the more negative side of the equation - the left side.

$$
\begin{array}{lcl} 
& \mathrm{NO}_{3}^{-}+2 \mathrm{H}^{+}+\mathrm{e}^{-} \rightarrow \mathrm{NO}_{2} \\
\text { charge: } & (-1 \quad+2 \quad-1=0) 0
\end{array}
$$

## (d) Balance hydrogen by adding $\mathbf{H}_{\mathbf{2}} \mathrm{O}$ molecules.

Since we have two hydrogen atoms on the left and none on the right, we add one $\mathrm{H}_{2} \mathrm{O}$ molecule to the right.

$$
\mathrm{NO}_{3}^{-}+2 \mathrm{H}^{+}+\mathrm{e}^{-} \rightarrow \mathrm{NO}_{2}+\mathrm{H}_{2} \mathrm{O}
$$

## (e) Check to make sure that oxygen is balanced.

If it is, the half-equation is almost certainly balanced correctly with respect to both mass (atoms) and charge.

There are three oxygen atoms on the left and three on the right. Oxygen is balanced.

## 4. Combine the two half-equations in such a way as to eliminate electrons.

We generally do this by multiplying each half-equation by the number of electrons in the other half-equation:

$$
1 \times \text { oxidation eq.: } \quad \mathrm{Cu} \rightarrow \mathrm{Cu}^{2+}+2 \mathrm{e}^{-}
$$

$2 \times$ reduction eq.: $\quad 2 \mathrm{NO}_{3}^{-}+4 \mathrm{H}^{+}+2 \mathrm{e}^{-} \rightarrow 2 \mathrm{NO}_{2}+2 \mathrm{H}_{2} \mathrm{O}$

$$
\mathrm{Cu}(\mathrm{~s})+2 \mathrm{NO}_{3}^{-}(\mathrm{aq})+4 \mathrm{H}^{+}(\mathrm{aq}) \rightarrow \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{NO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}
$$

This equation is now balanced: one Cu atom is on both sides of the equation, two N atoms are on both sides, six O atoms are on both sides, and four H atoms are on both sides. The total charge is +2 on both sides of the equation.

## **Simplifying Balanced Equations **

- For an equation in acidic solution, there will sometimes be $\mathrm{H}_{2} \mathrm{O}$ molecules and $\mathrm{H}^{+}$ions on both sides of the equation. We want to cancel out the excess amounts of these. The equation we just balanced doesn't have any excess $\mathrm{H}_{2} \mathrm{O}$ molecules or $\mathrm{H}^{+}$ions, but in the equation
$2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+5 \mathrm{HSO}_{3}{ }^{-}(\mathrm{aq})+5 \mathrm{H}_{2} \mathrm{O}+16 \mathrm{H}^{+}(\mathrm{aq}) \rightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+5 \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})+8 \mathrm{H}_{2} \mathrm{O}+15 \mathrm{H}^{+}(\mathrm{aq})$
there are both excess $\mathrm{H}_{2} \mathrm{O}$ molecules and $\mathrm{H}^{+}$ions. After canceling five $\mathrm{H}_{2} \mathrm{O}$ molecules and fifteen $\mathrm{H}^{+}$ions from both sides of the equation
$2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+5 \mathrm{HSO}_{3}{ }^{-}(\mathrm{aq})+5 \mathrm{H}_{2} \mathrm{O}+16 \mathrm{H}^{+}(\mathrm{aq}) \rightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+5 \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})+8 \mathrm{H}_{2} \sigma+15 \mathrm{H}^{+}(\mathrm{aq})$
we have

$$
2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+5 \mathrm{HSO}_{3}{ }^{-}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}) \rightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+5 \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}
$$

In basic solution, there will sometimes be $\mathrm{H}_{2} \mathrm{O}$ molecules and $\mathrm{OH}^{-}$ions on both sides of the equation. We want to cancel as many of them as possible. For example, in the equation

$$
3 \mathrm{ClO}^{-}(\mathrm{aq})+2 \mathrm{NO}(\mathrm{~g})+8 \mathrm{OH}^{-}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O} \rightarrow 3 \mathrm{Cl}^{-}(\mathrm{aq})+2 \mathrm{NO}_{3}^{-}(\mathrm{aq})+6 \mathrm{OH}^{-}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{O}
$$

we can cancel six $\mathrm{OH}^{-}$ions and three $\mathrm{H}_{2} \mathrm{O}$ molecules

$$
3 \mathrm{ClO}^{-}(\mathrm{aq})+2 \mathrm{NO}(\mathrm{~g})+8 \mathrm{H}^{-}(\mathrm{aq})+3 \mathrm{H}_{2} \sigma \rightarrow 3 \mathrm{Cl}^{-}(\mathrm{aq})+2 \mathrm{NO}_{3}^{-}(\mathrm{aq})+6 \mathrm{H}^{-}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{O}
$$

resulting in

$$
3 \mathrm{ClO}^{-}(\mathrm{aq})+2 \mathrm{NO}(\mathrm{~g})+2 \mathrm{OH}^{-}(\mathrm{aq}) \rightarrow 3 \mathrm{Cl}^{-}(\mathrm{aq})+2 \mathrm{NO}_{3}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}
$$

- In a few cases, we find that the final equation doesn't have the smallest whole number coefficients possible. In the equation

$$
6 \mathrm{Cl}_{2}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O} \rightarrow 10 \mathrm{Cl}^{-}(\mathrm{aq})+2 \mathrm{ClO}_{3}^{-}(\mathrm{aq})+12 \mathrm{H}^{+}(\mathrm{aq})
$$

we divide each coefficient by two to obtain the smallest whole number coefficients:

$$
3 \mathrm{Cl}_{2}(\mathrm{~g})+3 \mathrm{H}_{2} \mathrm{O} \rightarrow 5 \mathrm{Cl}^{-}(\mathrm{aq})+\mathrm{ClO}_{3}^{-}(\mathrm{aq})+6 \mathrm{H}^{+}(\mathrm{aq})
$$

## Summary of the Half-equation Method for Balancing Redox Reactions

1. Assign oxidation numbers to each atom in the equation. Split the equation into two half equations:
oxidation half equation - element increases in oxidation number reduction half-equation - element decreases in oxidation number
2. Balance one of the half-equations with respect to both atoms and charge using the following steps:
a. Balance the atoms of the element being oxidized or reduced
b. Balance the oxidation number by adding electrons, $\mathrm{e}^{-}$.
c. Balance the charge with $\mathrm{H}^{+}$ions in acidic solution, $\mathrm{OH}^{-}$ions in basic solution.
d. Balance hydrogen with $\mathrm{H}_{2} \mathrm{O}$ molecules.
e. Check to make sure oxygen is balanced. If it is, the half-equation is probably balanced.
3. Balance the other half-equation by steps $2 \mathrm{a}-2 \mathrm{e}$.
4. Combine the half equations so electrons cancel. Multiply each half equation by the number of electrons in the other half equation. Suggestion for simplifying: First take out any common factor, e.g., divide $4 \mathrm{e}^{-}$and $6 \mathrm{e}^{-}$by 2 .

- Cancel excess $\mathrm{H}^{+}$ions and $\mathrm{H}_{2} \mathrm{O}$ molecules in acidic solution or excess $\mathrm{OH}^{-}$ions and $\mathrm{H}_{2} \mathrm{O}$ molecules in basic solution.
- Make sure that the equation has the smallest whole-number coefficients. If not, divide each coefficient by the largest common factor. See page 5 for an example.
